

ABSTRACT

5 A method and apparatus are provided for analyzing a user's communication
activity to determine presence patterns at one or more communication devices. A user's
presence at one or more communication devices is monitored over time to detect at least one
pattern of behavior indicating that a user is likely to be present at a given communication device
during a particular time interval. Once a presence pattern is detected, a call that is destined for
the user during the associated time interval can be automatically routed to the user at the given
10 communication device. As a transition between each presence pattern is reached, i.e., when the
user changes locations or devices, the probability of the user being present on one device
decreases while the probability of the user being present on another device increases. According
to another aspect of the present invention, the presence call processor can optionally send
messages to multiple devices during these transitional times to ensure that the call is received by
15 the intended recipient.
